

Coffee and Heart Health: A Cohort Study

SAMPLE DOCUMENT prepared for the ProofLens demo. Fictional data.

Summary

This observational cohort study followed 12,400 adults for eight years to examine whether daily coffee drinking is related to heart disease.

Results

Adults who drank two or more cups of coffee per day had an 18% lower incidence of heart disease than adults who drank none.

Daily coffee consumption was associated with a lower risk of heart disease. The association remained after adjusting for age, smoking and exercise.

Limitations

Because this was an observational study, the findings do not establish that coffee causes a lower risk of heart disease. Unmeasured factors, such as diet and income, may explain part of the association. A randomised controlled trial would be needed to test causation.
